Introduction
Gorlin-Goltz syndrome (also known as Gorlin syndrome or Gorlin’s syndrome, nevoid basal-cell carcinoma syndrome (NBCCS), basal-cell naevus syndrome, and multiple basal-cell carcinoma syndrome) is an autosomal dominant disorder with a high degree of penetrance and variable expressivity. It is characterised by basal cell carcinomas, odontogenic keratocysts, palmar and/or plantar pits, and ectopic calcifications of the falx cerebri. More than 100 minor criteria have been described.

“The presence of two major and one minor criteria or one major and three minor criteria are necessary to establish a diagnosis. Early diagnosis and treatment of Gorlin-Goltz syndrome, as well as family screening and genetic counselling are essential as it may be associated in 10% of the patients with aggressive basal cell carcinomas and malignant neoplasias.” (Jawa, et al.).

The pictures on the right show the multiple typical Basal Cell Carcinoma (BCC) on the face of the patient as well as the palmar pits in the palm of the hand.

“In a busy community practice, clinical skin findings can often be misinterpreted. Skin cancers can sometimes mimic rashes like psoriasis, eczema or prurigo nodularis in both appearance and symptoms. Gorlin syndrome is one such genetic syndrome, characterized by the eruption of multiple and early onset basal cell carcinomas (BCCs), which can be mistaken for a rash. We describe a 68-year-old female who presented to the dermatology office with a previous history of over 30 BCCs that had been previously biopsied and/or surgically removed. However, the patient had been lost to follow up for several years and had not been seen by a skin specialist. In the interim, she had been...
misdiagnosed as having eczematous or psoriatic lesions by primary care providers. Patients with Gorlin syndrome are even harder to diagnose as their skin cancers often do not possess the classic features associated with a basal cell or squamous cell carcinoma. When in doubt, and especially if failing topical therapy, patients presenting with dermatological lesions should be properly referred to a specialist for further assessment and workup.”

Gorlin-Goltz Syndrome, is an inherited medical condition involving defects within multiple body systems such as the skin, nervous system, eyes, endocrine system, and bones. People with this syndrome are particularly prone to developing a common and usually non-life-threatening form of non-melanoma skin cancers.

About 10% of people with the condition do not develop basal cell carcinomas (BCCs).

Hasan A. & Akintola, D. 2018. “Gorlin-Goltz syndrome encompasses a variety of clinical signs and symptoms including important oral manifestations which general dental practitioners should be aware of. In light of the risk of malignancy it is important to be aware of this syndrome and recognise the need for early referral for multidisciplinary management.”

Scalia, A.C., Farulla, A., Fiocchi, F., Albaoni, C. & Torricelli, P. 2018. “Gorlin-Goltz Syndrome also known as Nevoid Basal Cell Carcinoma Syndrome is an autosomal dominant multisystem disorder. It is characterized by basal cell carcinomas, odontogenic keratocysts, skeletal abnormalities and in a minority of female patients bilateral calcified ovarian fibromas. It is challenging to radiologically assess ovarian fibromas as they have similar imaging patterns to some malignant ovarian lesions. However, it is vitally important to differentiate between benign and malignant lesions to determine patients’ suitability for fertility-sparing surgery.”

Incidence of Gorlin-Goltz Syndrome in South Africa
The National Cancer Registry (2014) does not provide any information regarding Gorlin-Goltz Syndrome in South Africa.

Signs, Symptoms and Diagnosis of Gorlin-Goltz Syndrome
The most common symptom of Gorlin-Goltz syndrome is the development of basal cell carcinoma early in adolescence or young adulthood. Gorlin-Goltz syndrome is also responsible for the development of other cancers early in life, including:

- medulloblastoma
- breast cancer
- non-Hodgkin’s lymphoma
- ovarian cancer

People who have basal cell nevus syndrome often have unique physical features as well. Examples include:
- pitting in the palms of the hands or on the feet
- large head size
- cleft palate
- eyes that are spaced far apart
- a protruding jaw
- spinal problems, including scoliosis or kyphosis

Some people with basal cell nevus syndrome will also develop tumours in their jaw. These tumours are known as keratocystic odontogenic tumours and can cause the person’s face to swell. In some instances, the tumours will displace the teeth.

If the condition is severe, additional symptoms may result. For example, it can affect the nervous system. This can cause:
- blindness
- deafness
- seizures
- mental retardation

The doctor can diagnose Gorlin-Goltz Syndrome. He or she will ask about the patient’s health history, if ever diagnosed with cancer, and if there is a history of the disease in the family. The doctor will also perform a physical examination to see for any of the following:
- keratocystic odontogenic tumours
- fluid on the brain that leads to head swelling (hydrocephalus)
- abnormalities in the ribs or spine

To confirm the diagnosis, the doctor may also order additional tests including:
- an echocardiogram
- MRI of the head
- biopsy (if you have tumors)
- X-ray of the head and jaw
- genetic testing

A diagnosis of Gorlin-Goltz syndrome can be made if there are 2 major or 1 major and 2 minor criteria.

**Major criteria**
- Multiple (>2) basal cell carcinomas at any age or one basal cell carcinoma less than 20 years or >10 basal cell naevi
- Histologically proven odontogenic keratocyst or a polyostotic bone cyst
- Palmar or plantar pits (3 or more)
• Ectopic calcification: lamellar or early (<20 years) calcification of the falx cerebri
• Family history of Gorlin-Goltz syndrome

Minor criteria
• Congenital skeletal defects: bifid, fused, splayed, or missing rib, or bifid, wedged, or fused vertebra
• Large head with occipitofrontal circumference >97th percentile, with frontal bossing
• Cardiac or ovarian fibroma (benign tumour in heart or ovary)
• Medulloblastoma (a malignant brain tumour that usually arises in young children)
• Lymphomesenteric cysts (abdominal cysts full of lymph fluid)
• Congenital malformation: cleft lip and/or palate, polydactyly (extra fingers or toes), congenital eye defect such as cataract, microphthalmos (small eye) or coloboma (iris tumour)

“Gorlin-Goltz syndrome (GGS), also known as nevoid basal cell carcinoma syndrome, is an autosomal dominant inherited disorder with high penetrance and variable expressivity. The classic triad originally described by Gorlin and Goltz in 1960 is composed of multiple nevoid basalcell carcinomas (NBCCs), odontogenic keratocysts (OKCs) in the jaws and bifid ribs. in 1977, this triad was modified by Rayner et al, and to GGS diagnosis, the OKCs had to appear in combination with calcification of the cerebellar falx or palmar and plantar pits. It may occur that although GGS syndrome is a well-known condition, only the specific symptom could be observed by different specialists. Therefore, the patient cannot be placed in an always complex clinical panel. The authors introduce an example in this report. In the present case, the patient had NBCCs, OKCs, and probably other signs of GGS since 1998, and has been treated for this conditions separated, without a diagnosis of a syndromic condition. A 54-year-old white woman was referred to the oral medicine service due to cyst located in the right mandibular body. She had history of skin cancer and undergone surgeries and radiotherapies for the lesions treatment, scars on the skin face due to the lesions removed, and a new ulcerated lesion on the back was diagnosed. In addition, the patient presented frontal and parietal bossing leading to increased cranial circumference, hypertelorism, strabismus, broad base, and mandibular prognathism. To the image examination, skull radiography revealed calcification of the falx cerebri; on chest X-ray bifid rib was observed and spine radiography showed vertebral osteophytes. Panoramic radiograph showed a well-defined bilocular radiolucent image located in posterior and anterior mandibular region. The whole elements induced us to investigate the patient’s past medical history, which revealed that since 1998 had the diagnosis of NBCC and OKC. A multidisciplinary approach becomes necessary for the diagnosis and follow-up of patients with GGS, considering the complexity of the clinical manifestations. Therefore, it is of primary importance for dental surgeons and dermatologists to know the signs and symptoms of GGS to perform early diagnosis and to avoid progression of the oral cysts or metastasis of the skin lesions.”

Manifestations of Gorlin-Goltz Syndrome
Gorlin-Goltz syndrome is a condition that affects many areas of the body and increases the risk of developing various cancerous and non-cancerous tumours.

In people with Gorlin-Goltz syndrome, the type of cancer diagnosed most often is basal cell carcinoma, which is the most common form of skin cancer. Individuals with Gorlin-Goltz syndrome typically begin to develop basal cell carcinomas during adolescence or early adulthood. These
cancers occur most often on the face, chest, and back. The number of basal cell carcinomas that develop during a person's lifetime varies among affected individuals. Some people with Gorlin-Goltz syndrome never develop any basal cell carcinomas, while others may develop thousands of these cancers. Individuals with lighter skin are more likely to develop basal cell carcinomas than are people with darker skin.

Most people with Gorlin-Goltz syndrome also develop non-cancerous (benign) tumours of the jaw, called keratocystic odontogenic tumours. These tumours usually first appear during adolescence, and new tumours form until about age 30. Keratocystic odontogenic tumours rarely develop later in adulthood. If untreated, these tumours may cause painful facial swelling and tooth displacement.

Individuals with Gorlin-Goltz syndrome have a higher risk than the general population of developing other tumours. A small proportion of affected individuals develop a brain tumour called medulloblastoma during childhood. A type of benign tumour called a fibroma can occur in the heart or in a woman's ovaries. Heart (cardiac) fibromas often do not cause any symptoms, but they may obstruct blood flow or cause irregular heartbeats (arrhythmia). Ovarian fibromas are not thought to affect a woman's ability to have children (fertility).

**The Sun and Gorlin-Goltz Syndrome**

Individuals with Gorlin-Goltz Syndrome have an increased sensitivity to radiation, including radiation from the sun. This means that they need to take extra care in the sun. This is the same for anyone with Gorlin-Goltz syndrome, whether they have had a skin cancer or not. Sufferers should always use a high factor sunscreen (SPF 50) and cover up properly in the sun.

**Treatment of Gorlin-Goltz Syndrome**

Treatment of patients with Gorlin-Goltz syndrome involves surveillance for and treatment of the associated findings. Because most of the findings involve tumours (benign and malignant), treatment is often surgical.

 Patients with Gorlin-Goltz syndrome often require surgery to remove jaw cysts in their 20s. Often, it is not until they are in their 30s or 40s that the basal cell carcinomas begin to appear so the diagnosis of the syndrome is often delayed.

All patients with Gorlin-Goltz syndrome should see a dermatologist for regular skin examinations so that basal cell carcinomas can be treated when they are small. This may require surgery or one of the many other treatments available for these tumours including cryotherapy, photodynamic therapy, fluorouracil cream and imiguimod cread. They should not receive treatment with irradiation as this is liable to provoke the development of more tumours.

Some patients may require long term treatment with oral retinoids such as isotretinoin or acitretin. Advanced basal cell carcinomas may sometimes be treated with vismodegib.

Sun protection is vital to reduce the number of skin cancers developing but even complete protection will not prevent all basal cell carcinomas in patients with Gorlin-Goltz syndrome.
About Clinical Trials
Clinical trials are research studies that involve people. They are conducted under controlled conditions. Only about 10% of all drugs started in human clinical trials become an approved drug.

Clinical trials include:
- Trials to test effectiveness of new treatments
- Trials to test new ways of using current treatments
- Tests new interventions that may lower the risk of developing certain types of cancers
- Tests to find new ways of screening for cancer

The South African National Clinical Trials Register provides the public with updated information on clinical trials on human participants being conducted in South Africa. The Register provides information on the purpose of the clinical trial; who can participate, where the trial is located, and contact details.
